## Homework Assignment No. 13 - Solutions

## Problem 1-(10 points)

A differential CMOS amplifier using depletion mode input devices is shown. Assume that the normal MOSFETs parameters are $K_{N}{ }^{\prime}=110 \mathrm{~V} / \mu \mathrm{A}^{2}, V_{T N}=$ $0.7 \mathrm{~V}, \lambda_{N}=0.04 \mathrm{~V}^{-1}$ and for the PMOS transistors are $K_{P}{ }^{\prime}=110 \mathrm{~V} / \mu \mathrm{A}^{2}, V_{T P}=0.7 \mathrm{~V}, \lambda_{P}=0.04 \mathrm{~V}^{-1}$. For the depletion mode NMOS transistors, the parameters are the same as the normal NMOS except that $V_{T N}=-0.5 \mathrm{~V}$. (a.) What is the maximum input common-mode voltage, $V_{i c m}{ }^{+}(\max )$ ? (b.) What is the minimum input common-mode voltage, $V_{i c m}{ }^{-}(\mathrm{min})$ ? (c.) What value of $V_{D D}$ gives an $I C M R=0.5 V_{D D}$ ?

## Solution

(a.) $\quad V_{i c m}{ }^{+}(\max )=V_{D D}-V_{S D 3}(\mathrm{sat})-V_{D S 1}(\mathrm{sat})+V_{G S 1}(50 \mu \mathrm{~A})$

$$
\begin{array}{ll} 
& i_{D}=\frac{\beta}{2}\left(V_{G S 1^{-}} V_{T 1}\right)^{2} \rightarrow \quad V_{G S 1}=\sqrt{\frac{2 i_{D}}{\beta}}+V_{T 1}=V_{D S 1}(\mathrm{sat})+V_{T 1} \\
\therefore \quad & V_{i c m}^{+}(\max )=V_{D D}-V_{S D 3}(\mathrm{sat})+V_{T 1}=V_{D D}-\sqrt{\frac{2 I_{D 3}}{\beta_{3}}}+V_{T 1} \\
& V_{\text {icm }}{ }^{+}(\max )=V_{D D}-0.4472-0.5=\underline{\underline{V}} \underline{\underline{D D}} \underline{\underline{-0.9472}}
\end{array}
$$

(b.) $\quad V_{i c m}{ }^{-}(\min )=V_{D S 5}(\mathrm{sat})+V_{G S 1}(50 \mu \mathrm{~A})=V_{D S 5}(\mathrm{sat})+V_{D S 1}(\mathrm{sat})+V_{T 1}$

$$
V_{i c m}^{-}(\mathrm{min})=\sqrt{\frac{2 I_{D 5}}{\beta_{5}}}+\sqrt{\frac{2 I_{D 1}}{\beta_{1}}}+V_{T 1}=0.1348+0.0953-0.5=\underline{\underline{-0.2698 \mathrm{~V}}}
$$

(c.) $\quad I C M R=V_{i c m}{ }^{+}(\max )-V_{i c m}{ }^{-}(\min )=V_{D D}-0.9472+0.2698=V_{D D}-0.6774$

$$
\therefore \quad V_{D D}-0.6774=0.5 V_{D D} \quad \rightarrow \quad V_{D D}=2(0.6774)=\underline{\underline{1.355 V}}
$$

## Problem 2-(10 points)

If the poles of a two-stage comparator are both equal to $-10^{7}$ radians $/ \mathrm{sec}$., find the maximum slope and the time it occurs if the magnitude of the input step is $10 V_{i n}(\mathrm{~min})$ and $V_{O H}-V_{O L}=1 \mathrm{~V}$. What must be the $S R$ of this comparator to avoid slewing?

## Solution

The response to a step response to the above comparator can be written as,

$$
v_{\text {out }},=1-e^{-t_{n}}-t_{n} e^{-t_{n}} \quad \text { where } v_{\text {out }},=\frac{v_{\text {out }}}{A_{\nu}(0) V_{\text {in }}} \text { and } t_{n}=t p_{1}
$$

To find the maximum slope, differentiate twice and set to zero.

$$
\begin{aligned}
& \frac{d v_{\text {out }}}{d t_{n}}=e^{-t_{n}}+t_{n} e^{-t_{n}}-e^{-t_{n}}=t_{n} e^{-t_{n}} \\
& \frac{d^{2} v_{\text {out }}}{d t_{n}{ }^{2}}=-t_{n} e^{-t n}+e^{-t_{n}}=0 \quad \Rightarrow \quad\left(1-t_{n}\right) e^{-t n}=0 \quad \Rightarrow \quad t_{n}(\max )=t p_{1}=1 \\
& \therefore \quad t_{n}(\max )=1 \mathrm{sec} \quad \text { and } t(\max )=\frac{t_{n}}{\left|p_{1}\right|}=\frac{1}{10^{7}}=\underline{\underline{0.1} \mu \mathrm{~s}} \\
& \frac{d v_{\text {out }}{ }^{\prime}(\max )}{d t_{n}}=e^{-1}=0.3679 \mathrm{~V} / \mathrm{sec} \quad \text { or } \quad \frac{d v_{\text {out }}{ }^{\prime}(\max )}{d t_{n}}=3.679 \mathrm{~V} / \mu \mathrm{s} \\
& \frac{d v_{\text {out }}{ }^{\prime}(\max )}{d t}=10\left(V_{O H^{-}} V_{\text {OL }}\right) \cdot \frac{d v_{\text {out }}{ }^{\prime}(\max )}{d t_{n}}=\underline{\underline{36.79 \mathrm{~V} / \mu \mathrm{s}}}
\end{aligned}
$$

$\therefore$ Therefore, the slew rate of the comparator should be greater than $36.79 \mathrm{~V} / \mu \mathrm{s}$ to avoid slewing.

## Problem 3-(10 points)

Repeat Ex. 8.2-5 with $v_{G 2}$ constant and the waveform of Fig. 8.2-6 applied to $v_{G 1}$.

## Solution

Output fall time, $t_{r}$ :
The initial states are $v_{o 1} \approx-2.5 \mathrm{~V}$ and $v_{o u t} \approx 2.5 \mathrm{~V}$. The reasoning for $v_{o 1}$ is interesting and should be understood. When $V_{G 1}=-2.5 \mathrm{~V}$ and $V_{G 2}=0 \mathrm{~V}$, the current in M1 is zero. This means the current is also zero in M4. Therefore, $v_{o 1}$ goes very negative and as M2 acts like a switch with $V_{D S} \approx 0$. Since the only current for M3 comes through M 2 and from $C_{I}$, the voltage across M 3 eventually collapses and $I_{3}$ becomes zero which causes $v_{o 1} \approx-2.5 \mathrm{~V}$.

From Example $8.2-5$, the trip point of the second stage is 1.465 V , therefore the rise time of the first stage is,

$$
t_{r 1}=0.2 \mathrm{pF}\left(\frac{1.465+2.5}{30 \mu \mathrm{~A}}\right)=26.4 \mathrm{~ns}
$$

The fall time of the second stage is found in Example 8.2-5 and is $t_{f 2}=53.4 \mathrm{~ns}$. The total output fall time is

$$
\therefore \quad t_{r}=t_{r 1}+t_{f 2}=\underline{\underline{79.8 \mathrm{~ns}}}
$$

Output rise time, $t_{r}$ :
The initial states for this analysis are $v_{o 1} \approx 2.5 \mathrm{~V}$ and $v_{\text {out }} \approx-2.5 \mathrm{~V}$.
The input stage fall time is,

$$
t_{f 1}=0.2 \mathrm{pF}\left(\frac{2.5-1.465}{30 \mu \mathrm{~A}}\right)=6.9 \mathrm{~ns}
$$

The output stage rise time is found by determining the best guess for $V_{G 6}$. Since $V_{G 6}$ is going from 1.465 to -2.5 V , let us approximate $V_{G 6}$ as

$$
\begin{aligned}
& \quad V_{G 6} \approx 0.5(1.465-2.5)=-0.5175 \quad \Rightarrow \quad V_{S G 6}=2.5-(-0.5175)=3.0175 \mathrm{~V} \\
& \therefore I_{6}=\frac{1}{2} K_{P}\left(\frac{W_{6}}{L_{6}}\right)\left(V_{S G 6}-\left|V_{T P}\right|\right)^{2}=0.5 \cdot 50 \times 10^{-6.38(3.0175-0.7)^{2}}=5102 \mu \mathrm{~A} \\
& \\
& t_{r 2}=5 \mathrm{pF}\left(\frac{2.5}{5102 \mu \mathrm{~A}-234 \mu \mathrm{~A}}\right)=2.6 \mathrm{~ns}
\end{aligned}
$$

The total output rise time is,
$\therefore t_{r}=t_{f 1}+t_{r 2}=\underline{\underline{9.5 n s}}$
The propagation time delay of the comparator is,

$$
t_{p}=t_{r}+t_{r}=\underline{\underline{44.7 \mathrm{~ns}}}
$$

## Problem 4-(10 points)

The comparator shown has an input applied as shown. Assuming the the pulse width is wide enough, calculate the propagation delay time for this comparator. Assume that the trip point of the output is at 0 V .

## Solution

When $v_{i n}=-1 \mathrm{~V}, i_{D 1}<i_{D 2}$, which gives $i_{D 6}>i_{D 7}$. Therefore $v_{o}\left(0^{-}\right)=$ +2.5 V . When $v_{i n}$ switches from -1 V to +1 V all of the $50 \mu \mathrm{~A}$ flows through M1 and is mirrored via M3-M8 and M9-M7 and multiplied by 10 to give $i_{7}$ $=500 \mu \mathrm{~A}$. Thus, the falling
 propagation delay time is found as,

$$
t_{p}{ }^{-}=\frac{C \cdot \Delta V}{i_{7}}=\frac{25 \mathrm{pF} \cdot 2.5 \mathrm{~V}}{500 \mu \mathrm{~A}}=125 \mathrm{~ns}
$$

Similarily, when $v_{\text {in }}=+1 \mathrm{~V}, v_{o}$ is at -2.5 V . When $v_{\text {in }}$ switches back to -1 V , all of the $50 \mu \mathrm{~A}$ of M5 flows through M2 giving $i_{6}=500 \mu \mathrm{~A}$ and $i_{7}=0$. The rising propagation delay time is

$$
t_{p}^{+}=\frac{C \cdot \Delta V}{i_{6}}=\frac{25 \mathrm{pF} \cdot 2.5 \mathrm{~V}}{500 \mu \mathrm{~A}}=125 \mathrm{~ns}
$$

Consequently, the propagation delay time for this comparator is

$$
\underline{\underline{t}} \underline{\underline{p}=0.5\left(t_{p}^{-}\right.} \underline{\underline{-}+t_{\underline{p}}^{+}} \underline{\underline{+})=125 \mathrm{~ns}}
$$

## Problem 5

If the folded-cascode op amp shown having a small-signal voltage gain of $7464 \mathrm{~V} / \mathrm{V}$ is used as a comparator, find the dominant pole if $C_{L}=5 \mathrm{pF}$. If the input step is 10 mV , determine whether the response is linear or slewing and find the propagation delay time. Assume the parameters of the NMOS transistors are $K_{N}^{\prime}=110 \mathrm{~V} / \mu \mathrm{A}^{2}, V_{T N}=0.7 \mathrm{~V}, \lambda_{N}=0.04 \mathrm{~V}^{-1}$ and for the PMOS transistors are $K_{P}{ }^{\prime}=50 \mathrm{~V} / \mu \mathrm{A}^{2}, V_{T P}=-0.7 \mathrm{~V}, \lambda_{P}=0.05 \mathrm{~V}^{-1}$.

## Solution

$V_{O H}$ and $V_{O L}$ can be found from many approaches. The easiest is simply to assume that $V_{O H}$ and $V_{O L}$ are 2.5 V and -2.5 V , respectively. However, no matter what the input, the values of $V_{O H}$ and $V_{O L}$ will be in the following range,

$$
\left(V_{D D^{-2}} V_{O N}\right)<V_{O H}<V_{D D} \quad \text { and } \quad V_{D D}<V_{O H}<\left(V_{S S}+2 V_{O N}\right)
$$

The reasoning is as follows, suppose $V_{i n}>0$. This gives $I_{1}>I_{2}$ which gives $I_{6}<I_{7}$ which gives $I_{9}<I_{7} . V_{\text {out }}$ will increase until $I_{7}$ equals $I_{9}$. The only way this can happen is for M5 and M 7 to leave saturation. The same reasoning holds for $V_{i n}<0$.

Therefore assuming that $V_{O H}$ and $V_{O L}$ are 2.5 V and -2.5 V , respectively, we get

$$
V_{i n}(\min )=\frac{5 \mathrm{~V}}{7464}=0.67 \mathrm{mV} \rightarrow \quad k=\frac{10 \mathrm{mV}}{0.67 \mathrm{mV}}=14.93
$$

## Problem 5 - Continued

The folded-cascode op amp as a comparator can be modeled by a single dominant pole. This pole is found as,

$$
\begin{gathered}
p_{1}=\frac{1}{R_{\text {out }} C_{L}} \text { where } R_{\text {out }} \approx g_{m 9} r_{d s 9} r_{d s 11} \|\left[g_{m 7} r_{d s 7}\left(r_{d s 2} \| r_{d s 5}\right)\right] \\
g_{m 9}=\sqrt{2 \cdot 75 \cdot 110 \cdot 36}=771 \mu \mathrm{~S}, g_{d s 9}=g_{d s 11}=75 \times 10^{-6} \cdot 0.04=3 \mu \mathrm{~S}, g_{d s 2}=50 \times 10^{-6}(0.04)=2 \mu \mathrm{~S} \\
g_{m 7}=\sqrt{2 \cdot 75 \cdot 50 \cdot 80}=775 \mu \mathrm{~S}, g_{d s 5}=125 \times 10^{-6} \cdot 0.05=6.25 \mu \mathrm{~S}, g_{d s 7}=50 \times 10^{-6}(0.05)=3.75 \mu \mathrm{~S} \\
g_{m 9} r_{d s 9} r_{d s 11}=(771 \mu \mathrm{~S})\left(\frac{1}{3 \mu \mathrm{~S}}\right)\left(\frac{1}{3 \mu \mathrm{~S}}\right)=85.67 \mathrm{M} \Omega \\
g_{m 7} r_{d s 7}\left(r_{d s 2^{2}} \| r_{d s 5} \approx(775 \mu \mathrm{~S})\left(\frac{1}{3.75 \mu \mathrm{~S}}\right)\left(\frac{1}{2 \mu \mathrm{~S}} \| \frac{1}{6.25 \mu \mathrm{~S}}\right)=25.05 \mathrm{M} \Omega,\right. \\
R_{\text {out }} \approx 85.67 \mathrm{M} \Omega \| 25.05 \mathrm{M} \Omega=19.4 \mathrm{M} \Omega
\end{gathered}
$$

The dominant pole is found as, $p_{1}=\frac{1}{R_{\text {out }} C_{L}}=\frac{1}{19.4 \times 10^{6} 5 \mathrm{pF}}=10,318 \mathrm{rps}$
The time constant is $\tau_{1}=96.9 \mu \mathrm{~s}$.
For a dominant pole system, the step response is, $v_{\text {out }}(t)=A_{v d}\left(1-e^{-t / \tau_{1}}\right) V_{\text {in }}$
The slope is the largest at $t=0$. Evaluating this slope gives,

$$
\frac{d v_{\text {out }}}{d t}=\frac{A_{v d}}{\tau_{1}} e^{-t / \tau_{1}} V_{\text {in }} \quad \text { For } t=0, \text { the slope is } \frac{A_{v d}}{\tau_{1}} V_{\text {in }}=\frac{7464}{96.9 \mu \mathrm{~s}}(10 \mathrm{mV})=0.77 \mathrm{~V} / \mu \mathrm{s}
$$

The slew rate of this op amp/comparator is $S R=\frac{I_{3}}{C_{L}}=\frac{100 \mu \mathrm{~A}}{5 \mathrm{pF}}=20 \mathrm{~V} / \mu \mathrm{s}$
Therefore, the comparator does not slew and its propagation delay time is found from the linear response as,

$$
t_{P}=\tau_{1} \ln \left(\frac{2 k}{2 k-1}\right)=96.9 \mu \mathrm{~s} \cdot \ln \left(\frac{2 \cdot 14.93}{2 \cdot 14.93-1}\right)=(96.9 \mu \mathrm{~s})(0.0341)=\underline{\underline{3.3 \mu \mathrm{~s}}}
$$
