#### Lecture 24

**MOSFET Basics (Understanding with no math)** 

Reading: Pierret 17.1-17.2 and Jaeger 4.1-4.10 and Notes

Georgia Tech ECE 3040 - Dr. Alan Doolittle

Flow of current from "Source" to "Drain" is controlled by the "Gate" voltage.

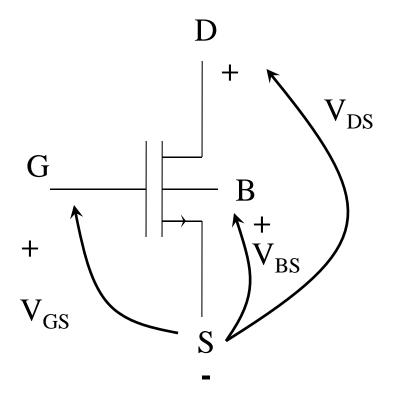

Control by the Gate voltage is achieved by modulating the conductivity of the semiconductor region just below the gate. This region is known as the channel

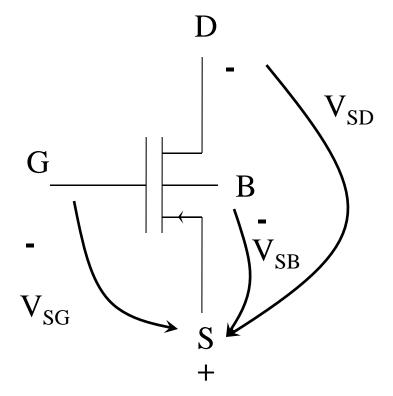

Georgia Tech ECE 3040 - Dr. Alan Doolittle

**Qualitative Description** 

n-channel MOS Transistor

p-channel MOS Transistor

Note: All voltages are shown in their "positive" direction. Obviously,  $V_{YX}$ =- $V_{XY}$  for any voltage

G=Gate, D=Drain, S=Source, B=Body (substrate, but to avoid confusion with substrate, B is used)

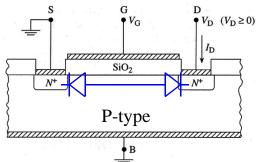

Georgia Tech

#### **Qualitative Description**

Assume an n-channel (receives it's name from the "type" of channel present when current is flowing) device with its source and substrate grounded (i. e.,  $V_S=V_B=0$  V).

For any value of V<sub>DS</sub>:

•when  $V_{GS}$  <0 (accumulation), the source to drain path consists of two back to back diodes. One of these diodes is always reverse biased regardless of the drain voltage polarity.

•when  $V_{GS} < V_T$  (depletion), there is a deficit of electrons and holes making the channel very highly resistive. => No Drain current can flow.

SiO<sub>2</sub>

High ρ due to
Depletion

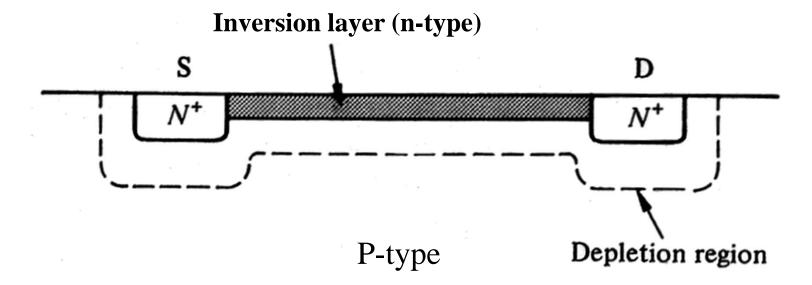

B

**Qualitative Description** 

Consider now the Inversion case:

First,  $V_{DS} = 0$ :

•when  $V_{GS} > V_T$ , an induced n- type region, an "inversion layer", forms in the channel and "electrically connects" the source and drain.

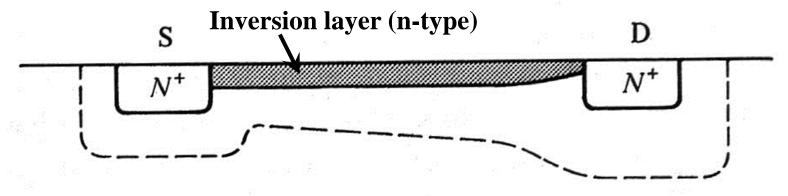

Georgia Tech

#### **Qualitative Description**

Inversion case,  $V_{GS} > V_{T(continued)}$ :

When  $V_{DS} > 0$ , the induced n- type region allows current to flow between the source and drain. The induced channel ast like a simple resistor. Thus, this current,  $I_D$ , depends linearly on the Drain voltage  $V_D$ . This mode of operation is called the linear or "triode"\* region.

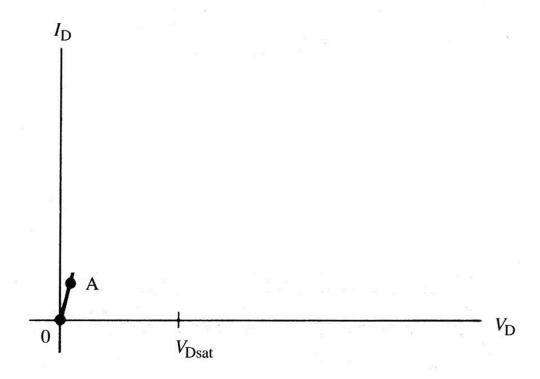

P-type

<sup>\* &</sup>quot;Triode" is a historical term from vacuum tube technology.

**Qualitative Description** 

Inversion case,  $V_{GS} > V_{T(continued)}$ :

Drain current verses drain voltage when in the linear or "triode" region.

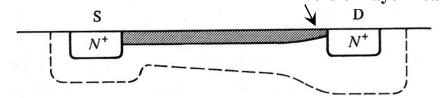

Georgia Tech

#### **Qualitative Description**

Inversion case,  $V_{GS} > V_{T(continued)}$ :

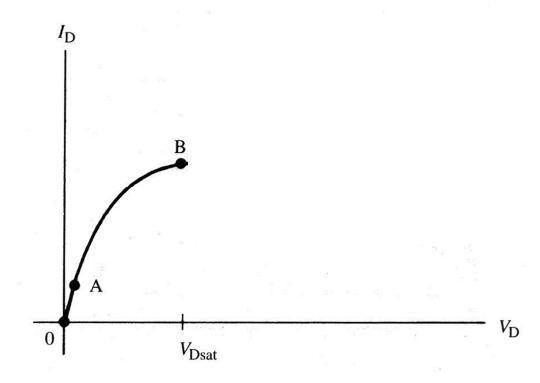

When  $V_{DS}$  increases a few tenths of a volt (>0):

- •The depletion region near the drain widens (N+ drain is positively biased I.e. reverse biased with respect to the substrate).
- •The electron concentration in the inversion layer near the drain decreases as they are "sucked out" by the Drain voltage.
- •Channel conductance decreases resulting in a drop in the slope of the  $I_D$ - $V_D$  curve. Reduced electron concentration in the Inversion layer near the drain

Inversion case,  $V_{GS} > V_{T(continued)}$ :

Drain current verses drain voltage for increasing  $V_{DS}$  (still in the "linear" or triode region).

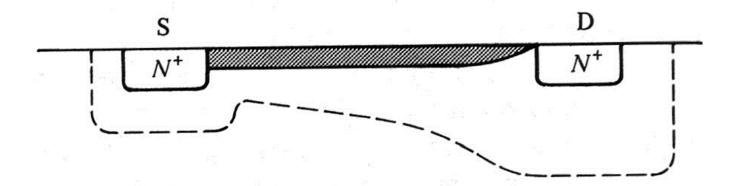

#### **Qualitative Description**

Inversion case,  $V_{GS} > V_{T}(continued)$ :

The inversion layer eventually vanishes near the drain end of the channel.

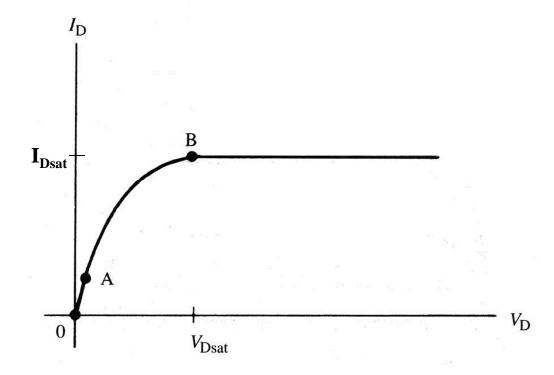

This is called "Pinch-Off" and results in a Flat I<sub>D</sub>-V<sub>DS</sub> curve

Inversion case,  $V_{GS} > V_{T}(continued)$ :

I<sub>D</sub>-V<sub>DS</sub> curve for the "Saturation Region"

The drain-source voltage,  $V_{DS}$ , at which this occurs is called the saturation voltage,  $V_{sat}$  while the current is called the saturation current,  $I_{Dsat}$ .

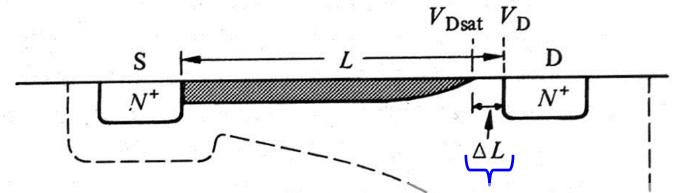

#### **Qualitative Description**

Inversion case,  $V_{GS} > V_{T}$ (continued):

For  $V_{DS} > V_{sat}$  the channel length, L, effectively changes by a value  $\Delta L$ .

The region of the channel,  $\Delta L$  is depleted and thus, is high resistivity. Accordingly, almost all voltage increases in  $V_{DS}>V_{sat}$  are "dropped across" this portion of the channel.

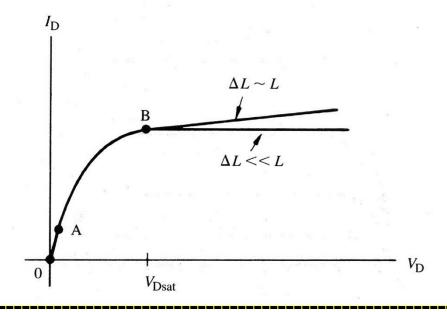

High electric fields in this region act similarly to the collector-base junction in a BJT in active mode, "stripping" or "collecting" carriers from the channel.

Georgia Tech

Inversion case,  $V_{GS} > V_{T}$ (continued):

If  $\Delta L \ll L$ , the voltage at the end of the channel will be constant  $(V_{sat})$  for all  $V_{DS} \gg V_{sat}$ .  $I_D$  will be constant.

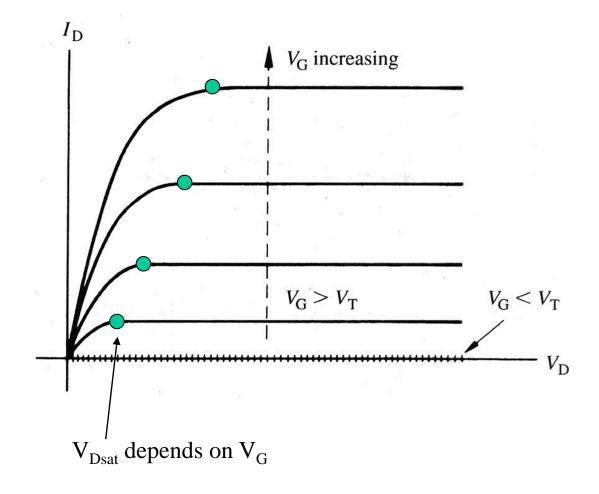

If  $\Delta L\sim L$ , the voltage dropped across the the channel  $(V_{SAT})$  varies greatly with  $V_{DS}$  due to large modulations in the electric field across the pinched off region ( $E=[V_{DS}-V_{SAT}]/[\Delta L]$ ). In this case,  $I_D$  increases slightly with  $V_{DS}$ .

Georgia Tech

Finally,

I<sub>D</sub>-V<sub>DS</sub> curves for various V<sub>GS</sub>:
